CERTIFICATE

This certificate is issued in support of an application for Patent registration in a country outside New Zealand pursuant to the Patents Act 1953 and the Regulations thereunder.

I hereby certify that annexed is a true copy of the Provisional Specification as filed on 15 July 2003 with an application for Letters Patent number 527022 made by MACPAC WILDERNESS EQUIPMENT LIMITED.

Dated 5 August 2004.

PROVISIONAL SPECIFICATION

IMPROVED PACK AND FRAME FOR PACK

We, MACPAC WILDERNESS EQUIPMENT LIMITED, a New Zealand Company of 11
Moncur Place, Riccarton, Christchurch, New Zealand, do hereby declare this invention
to be described in the following statement:

1 (followed by 1a)

Title: Improved Pack and Frame for Pack

Technical Field

5 The present invention relates to improvements in climber's or trumper's packs, and to frames for such packs.

Background Art

10 A modern pack consists of a sac in which equipment may be carried, the sac being mounted on a frame, and a shoulder harness secured to the sac or to the frame. Since carrying a heavy load supported only from the shoulders can lead to backache or even to back damage, a majority of modern packs also include a hip belt which is connected to the sac or the frame, generally at or close to the base of the sac, to transfer some of the
15 load from the shoulders to the hips.

Although using a hip belt reduces the strain on the back, the belt itself can cause problems to the wearer, due to the way in which the human body moves when walking.

20 When a human being walks, he leans backwards and forwards with each step (Fig. 1) and from side to side with each double step (Fig. 2). As he leans to the supporting side when taking a step the torso compresses on that side and extends on the stepping side (Fig. 3):- this means that, viewing the person from the front, the person's hips pivot up and down around an imaginary centre line (indicated in broken lines in Fig. 3). This is termed
25 'up and down' movement in the present specification. In addition, as shown in Fig. 4, the person's hips move with his legs, but his torso and arms swing in the opposite direction, with the body pivoting at the waist. In Fig. 4, a line through the shoulders is indicated by line S-S and a line through the hips is indicated by line H-H. As shown in Fig. 4, there is a considerable relative rotation between the shoulders (line S-S) and the hips (line H-H) with
30 each step. This is termed 'twisting' movement in the present specification.

Also, when a human being bends or steps up, his back extends:- the further the person

leans forwards, the longer his back becomes. This extension of the back is in a curved plane, following the natural curve of the back.

Because of the above described movements, a hip belt which is rigidly secured to the pack, and which therefore moves with the pack, is very uncomfortable for the wearer, because the hip belt is constantly rubbing against the wearer due to the relative movements of different parts of the wearer's body when walking. The hip belt cannot be loosened to prevent this rubbing, because the belt must fit snugly to transmit load to the wearer's pelvic girdle and relieve the load on his back. Fig. 5 of the accompanying drawings shows, in diagrammatic form, the effect of a person wearing a pack with a rigidly-secured hip-belt bending forwards;- the back extension raises the pack and lifts the hip-belt from the hips, applying uncomfortable pressure across the front of the lower abdomen (arrow P).

15 The above described problem was partially solved by the pivotal hip belt connection provided by New Zealand Patent No. 201751 (Macpac Wilderness Equipment Limited) dated 25th July 1983.

However, the hip belt described in New Zealand patent No. 201751 was not a complete solution to the problem:- because the hip belt was secured to the pack by a comparatively narrow connection, the load transfer from the pack to the hip belt was concentrated at the connection point and was distributed around the pelvic girdle of the wearer only by the stiffness of the hip belt. The more rigid the hip belt, the better the load transfer, but in general, the more rigid a hip belt is, the less comfortable it is to wear. Thus, the problem remained of providing a harness which permitted relative movement between the wearer's back and hips in at least three directions but which provided an efficient load transfer around the pelvic girdle of the wearer without resorting to the use of an uncomfortably stiff hip belt.

30 New Zealand Patent 335931 provides a frame and hip belt which give excellent weight transfer, but both the frame and the hip belt are bulky and thus comparatively heavy to wear, and are relatively expensive to manufacture.

Disclosure of Invention

It is an object of the present invention to provide a pack and a pack frame which are comparatively lightweight and thus simpler from a user's perspective, whilst also providing
5 efficient weight transfer from the pack to the hip belt.

The present invention provides an internal frame for a pack; said frame including a pair of spaced flexible rods positioned one on each side of the frame so as to extend down at least the lower part of the length of each side of the pack.

10 The present invention provides a pack which includes a sac, an internal frame for the sac, a shoulder harness and a hip belt; wherein the frame includes a pair of spaced flexible rods positioned one on each side of the frame so as to extend down at least the lower part of the length of each side of the sac; and wherein each rear lower side of the sac is
15 provided with a flexible wing to which the corresponding portion of the hip belt is secured; each wing being located relative to the corresponding flexible rod such that at least the lower end of said rod can move across said wing; and tensioning means secured between each flexible rod and the corresponding portion of the hip belt; each said tensioning means being adapted to move the corresponding flexible rod across the width of the
20 corresponding wing so as to provide a relatively rigid weight transmitting connection between the said rod and the corresponding portion of the hip belt.

Brief Description of Drawings

25 A preferred embodiment of the present invention is described in detail with reference to the accompanying drawings, in which:-

Fig.s 1-5 are diagrams showing the movement of the human body when walking;

Fig. 6 is a plan view of a pack frame in accordance with the present invention;

30 Fig. 7 is a side view of the frame of Fig. 6;

Fig. 8 is a diagrammatic side view of the frame of the present invention fitted into a pack;

Fig. 9 is a detail of Fig. 8 on a larger scale; and

Fig. 10 is a section on line X-X of Fig. 9, on a larger scale.

Best Mode for Carrying out the Invention

Referring in particular to Fig. 8, a climber's or trumper's pack 2 in accordance with the present invention comprises a sac 3 which is of known type (apart from the addition of wings 4 as hereinafter described) which is supported by an internal frame 5 and which is provided with a harness 6 which includes a pair of padded shoulder straps 7 and a hip belt 8. The harness 6 is of known type apart from the novel features of the hip belt as described below.

5 Referring in particular to Fig.s 6 and 7, the frame 5 consists of a pair of spaced U-shaped portions 10, 11 which are inclined at an acute angle to each other and are spaced apart by a crossbar 12. The curved end of each U-shaped portions 10,11 is uppermost, and when the frame is inserted into the sac 3, the U-shaped portions support the upper part of the sac.

10 Referring in particular to Fig.s 6 and 7, the frame 5 consists of a pair of spaced U-shaped portions 10, 11 which are inclined at an acute angle to each other and are spaced apart by a crossbar 12. The curved end of each U-shaped portions 10,11 is uppermost, and when the frame is inserted into the sac 3, the U-shaped portions support the upper part of the sac.

15 The outer leg 10a, 11a of each U-shaped portion is connected to a flexible rod 13,14, the longitudinal axis of which is aligned with the longitudinal axis of the corresponding leg.

20 The inner leg 10b, 11b of each U-shaped portion is formed integrally with a looped portion 15 which supports the lower portion of the sac and lies between the flexible rods 13,14.

The outer and inner legs 10a/b, 11a/b are tied together adjacent their lower ends by crossbars 10c,11c.

25 As shown in Fig. 7, each of the U-shaped portions 10,11 is curved in side view to accommodate the curve of a wearer's upper back, and the looped portion 15 also is curved to accommodate the shape of the wearer's lower back.

The frame 5 is secured inside the sac 3 in known manner, as shown in Fig. 8.

30 The sac 3 is of known design apart from the addition of a fabric wing at each lower rear corner of the sac. Each wing 4 is roughly triangular in shape, and includes two parallel pieces of fabric with padding sandwiched between them.

As shown more detail in Fig. 9, the side 4a of the wing which extends along the length of the back of the sac opens into that portion of the sac which receives the frame 5, and the corresponding flexible rod 13,14 lies within the wing 4, between the layers of padding.

5 Two parallel openings 16,17 into the interior of each wing 4 are formed in the outer edge 4c (e. furthest from the edge 4a), adjacent the lower edge 4b.

Each opening 16, which is closest to the edge 4c, receives one end 18 of the hip belt 8; the end 18 passes through the width of the wing 4 and is sewn to the sac adjacent the opening 16.

10

Each opening 17 receives an adjustment strap 19 which extends through the opening 17 and is secured at its inner end to the corresponding flexible rod 13,14 adjacent the lower end of the rod. Each strap 19 is secured to the corresponding flexible rod 13,14 by means 15 of a retainer 20 formed integrally with the rod. The outer end 21 of each adjustment strap 19 passes through a buckle 22 which is secured to the hip belt 8. For reasons of clarity, the buckle 22 is shown in Fig.s 9 and 10 as a simple 2- bar buckle, but in fact is an adjustment buckle of known type which allows each strap 19 to be pulled through the buckle in the direction of Arrow A (Fig. 10) but does not permit movement in the reverse 20 direction until the strap 19 is manually repositioned to allow reverse movement.

25

The above described pack is used as follows:- the pack is positioned on the wearer's shoulders in the usual way, and the hip belt is buckled around the wearer's hips. In the untensioned position shown in Fig. 9, the frame 5 is attached to the hip belt 8 by the wings 4 and the straps 19, all of which are free to flex and pivot relative to the frame:- this results in a flexible connection, but with relatively little weight transferred from the frame to the hip belt.

30

To increase the proportion of the weight of the pack which is transferred from the frame to the hip belt, the wearer pulls the straps 19 in the direction of Arrow A, pulling the flexible rods 13,14 in the direction of Arrow B. The adjustment buckles 22 hold the straps 19 in the tensioned position, retaining the flexible rods 13,14 in the position shown in hatch lines (14a in Fig. 9). This provides a much more rigid attachment between the frame and

the hip belt, and thus improves weight transfer to the hip belt.

The pack of the present invention is capable of providing efficient weight transfer to the hip belt, but is substantially simpler to manufacture and lighter in weight than comparable
5 designs.
